

MC**1. B**

Solution: The volume of the cuboid is $2 \times 4 \times 8 = 64$. We see that $4^3 = 64$ so the edge length of the cube is 4.

(Pascal 2006, #5)

2. D

Solution: Let the hypotenuse be c and the legs be a and b . By the Pythagorean theorem, $a^2 + b^2 = c^2$ so $1800 = a^2 + b^2 + c^2 = 2c^2$. Solving for c gives $c = \sqrt{(1800 / 2)} = \sqrt{900} = 30$.

(Cayley 2006, #18)

3. D

Solution: If \heartsuit is greater than 2, then its cube would be greater than 20. If $\heartsuit = 1$, then $\nabla = 1$ which is not distinct. Thus, $\heartsuit = 2$ and $\nabla = 8$ so $\nabla \times \nabla = 64$.

(Fermat 2018, #5)

4. B

Solution: 4Y means four yellow marbles, etc. So we have 8Y, 7R, 5B in the bag.

First we show that 8 fails. Taking 5R and 3B leaves 8Y, 2R, 2B in the bag which does not meet the criteria.

There are two ways of failing:

1. leaving less than 3 marbles of two colours (6Y, 1R, 2B fails)
2. leaving less than 4 marbles of each colour (3Y, 2R, 3B fails)

Every other configuration passes.

Let's try to fail by taking at most 7 marbles using the first way. Leaving less than 3 yellow, red and black marbles requires taking 6Y, 5R, 3R respectively. Adding any two of these exceeds 7 marbles so this is not possible.

Let's try the second way. Leaving less than 4 yellow, red and black marbles requires taking 5Y, 4R, 2R respectively. These add to taking 11 marbles in total which is not possible.

Thus, it is impossible to fail by taking 7 marbles or less.

(Fermat 2006, #20)

5. E

Solution: Let O be the center of the largest circle. Since O is on the circle centered at X , the radius of the largest circle is 2. Let r be the radius of the small circles.

Notice that by symmetry, the circles centered at Y and Z are tangent to the line XO at T .

We find that $XY = r + 1$, $XO = 1$, $OY = 2 - r$, $YT = r$.

Since YT is perpendicular to XO ,

$$OT^2 = OY^2 - YT^2 = (2 - r)^2 - r^2 = 4(1 - r).$$

We also see that,

$$XY^2 = YT^2 + XT^2$$

$$(r + 1)^2 = r^2 + (XO + OT)^2$$

$$2r + 1 = 1 + 2OT + OT^2$$

$$2r = 2OT + 4(1 - r)$$

$$3r - 2 = 0T$$

Thus,

$$4(1 - r) = (3r - 2)^2$$

$$4 - 4r = 9r^2 - 12r + 4$$

$$0 = 9r^2 - 8r$$

$$0 = r(9r - 8)$$

but since $r \neq 0$, $r = 8/9$ which is closest to 0.89.

(Fermat 2020, #24)

Word Problems

1. 4

Solution: From $12x = 4y + 2$ we see that $6x = 2y + 1$.

Multiplying this by 3 gives $18x = 6y + 3$ so $6y - 18x = -3$.

Thus, $6y - 18x + 7 = -3 + 7 = 4$.

(CIMC 2015, A4)

2. 3/4

Solution: Using 2 with $x = 0$ gives $f(0) = f(0)/2$ so $f(0) = 0$.

Using 1 with $x = 0$ gives $f(1) = 1 - f(0) = 1$.

Using 2 with $x = 1$ gives $f(1/3) = f(1)/2 = 1/2$.

Using 1 with $x = 1/3$ gives $f(2/3) = 1 - f(1/3) = 1/2$.

Using 2 with $x = 1/3$ gives $f(1/9) = f(1/3)/2 = 1/4$.

Using 1 with $x = 1/9$ gives $f(8/9) = 1 - f(1/9) = 3/4$.

Using 2 with $x = 2/3$ gives $f(2/9) = f(2/3)/2 = 1/4$.

Using 1 with $x = 2/9$ gives $f(7/9) = 1 - f(2/9) = 3/4$.

Using 3, we find that for all real numbers t between $7/9$ and $8/9$, $f(t) = 3/4$. (Why?)

Since $7/9 \leq 6/7 \leq 8/9$, $f(6/7) = 3/4$.

Note: f is the [Cantor function](#)

(CSMC 2020, A6)

3.

Solution:

$$\begin{aligned}
 1. \quad \text{add}(\text{one}, \text{two}) &= \text{add}(\text{one}, \text{succ}(\text{one})) \\
 &= \text{succ}(\text{add}(\text{one}, \text{one})) \\
 &= \text{succ}(\text{add}(\text{one}, \text{succ}(\text{zero}))) \\
 &= \text{succ}(\text{succ}(\text{add}(\text{one}, \text{zero}))) \\
 &= \text{succ}(\text{succ}(\text{one})) \\
 &= \text{three}
 \end{aligned}$$

All of the equal signs are true by *definition*.

$$\begin{aligned}
 2. \quad \text{add}(\text{zero}, \text{two}) &= \text{add}(\text{zero}, \text{two}) \\
 &= \text{add}(\text{zero}, \text{succ}(\text{one})) \\
 &= \text{succ}(\text{add}(\text{zero}, \text{one})) \\
 &= \text{succ}(\text{add}(\text{zero}, \text{succ}(\text{zero}))) \\
 &= \text{succ}(\text{succ}(\text{add}(\text{zero}, \text{zero}))) \\
 &= \text{succ}(\text{succ}(\text{zero})) \\
 &= \text{two}
 \end{aligned}$$

Again, all of the equal signs are true by *definition*.

3. Induct on n .

a. $n = \text{zero}$

$$\begin{aligned}
 \text{add}(\text{zero}, n) &= \text{add}(\text{zero}, \text{zero}) \\
 &= \text{zero} \\
 &= n
 \end{aligned}$$

b. Now suppose $\text{add}(\text{zero}, n) = n$.

We want to show that $\text{add}(\text{zero}, \text{succ}(n)) = \text{succ}(n)$.

$$\begin{aligned}
 \text{add}(\text{zero}, \text{succ}(n)) &= \text{succ}(\text{add}(\text{zero}, n)) \\
 &= \text{succ}(n)
 \end{aligned}$$

We replaced the **add**(zero, n) in the equation with n.

Note: This question gives a beginner's introduction to the [Peano axioms](#).

Note: Some questions have been slightly modified from the original.
